

Dear Hiring Team,

BVNC's design system role caught my attention for a specific reason. The framing around AI as a consumer of the system, not just a tool in the workflow, is something I've been thinking about and working on directly.

At Remuner I built the token repository infrastructure using Codex. Not to generate boilerplate, but to achieve a specific goal: full autonomy over the pipeline without depending on engineering for every change. I wrote the briefs, asked Codex to propose an approach ranked by impact, then reviewed and iterated. The output was real infrastructure: CI validation pipelines, deterministic drift checks, smoke tests, W3C multi-file token migration, and an HTML sandbox preview for token documentation. That work changed how I think about system design. Making the naming, structure, and documentation clean enough for a model and for any engineer or PM.

I've built two production systems from scratch. At Abacum I defined the token architecture and cross-squad governance for a fintech data platform, built the full pipeline with a dedicated engineer, and kept MUI as the base to focus effort on the token layer rather than low-level component work. At Remuner I did the same as the sole designer, this time with a deliberately smaller token set at the start. A minimal set is easier to govern and scale than a comprehensive one that never gets adopted.

The governance and advocacy work matters as much to me as the build work. At Abacum I put together the business case with the head of design, presented it to engineering leadership, and ran Maker Days to drive adoption across squads. Getting a system used is a different problem from building one.

The design systems case is at <https://manel-leiva.com/cases/design-systems>. Happy to walk through the token repository work in more detail.
