

Dear Hiring Team,

Hostaway's design system role caught my attention because of how the brief is framed. Building a system that AI can consume and generate against cleanly, while also integrating AI tooling into the design practice itself, is something I've been working on directly, not just thinking about.

At Remuner I built the token repository infrastructure using Codex. I wrote the briefs, Codex implemented step by step. The goal was specific: full autonomy over the pipeline without depending on engineering for every change. The output was real: CI validation pipelines, deterministic drift checks, smoke tests, W3C multi-file token migration, and an HTML sandbox preview for token documentation. That work changed how I think about system design. Making the naming, structure, and documentation clean enough for a model and any engineer or PM.

I've built two production systems from scratch. At Abacum I defined the token architecture and cross-squad governance for a fintech data platform, built the full pipeline with a dedicated engineer, and presented the business case to engineering leadership. At Remuner I did the same as the sole designer, applying a lesson from Abacum: start with a deliberately small token set. A minimal set is easier to govern and scale than a comprehensive one that never gets adopted. In both cases engineers consumed updates without needing to involve design.

The advocacy side matters as much to me as the build work. At Abacum I put together the business case with the head of design, presented it to engineering leadership, and ran Maker Days to drive adoption across squads. Getting a system used is a different problem from building one.

The design systems case is at <https://manel-leiva.com/cases/design-systems>. Happy to walk through the token repository work in more detail.
